Video of Demo Ghostbusters Markov Model (Reminder)

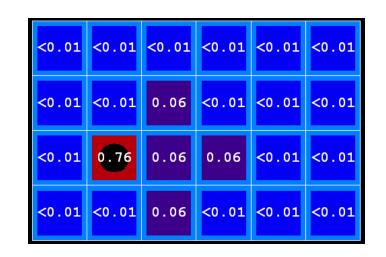

Recap: Filtering

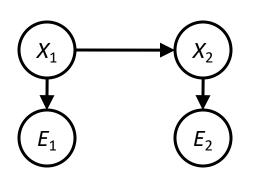

Elapse time: compute P($X_t \mid e_{1:t-1}$)

$$P(x_t|e_{1:t-1}) = \sum_{x_{t-1}} P(x_{t-1}|e_{1:t-1}) \cdot P(x_t|x_{t-1})$$

Observe: compute P($X_t \mid e_{1:t}$)

$$P(x_t|e_{1:t}) \propto P(x_t|e_{1:t-1}) \cdot P(e_t|x_t)$$

$$P(X_1)$$
 <0.5, 0.5> Prior on X_1

$$P(X_1 \mid E_1 = umbrella)$$
 <0.82, 0.18> *Observe*

$$P(X_2 \mid E_1 = umbrella)$$
 <0.63, 0.37> Elapse time

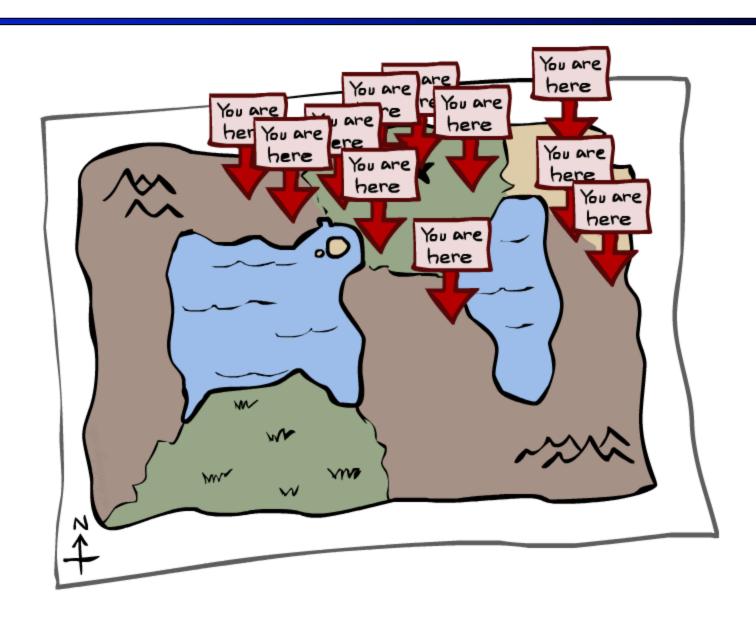

$$P(X_2 \mid E_1 = umb, E_2 = umb)$$
 <0.88, 0.12> Observe

Particle Filtering

Particle Filtering

- Filtering: approximate solution
- Sometimes |X| is too big to use exact inference
 - |X| may be too big to even store P(X)
 - E.g. X is continuous
- Solution: approximate inference
 - Track samples of X, not all values
 - Samples are called particles
 - Time per step is linear in the number of samples
 - But: number needed may be large
 - In memory: list of particles, not states
- This is how robot localization works in practice
- Particle is just new name for sample

0.0	0.1	0.0
0.0	0.0	0.2
0.0	0.2	0.5

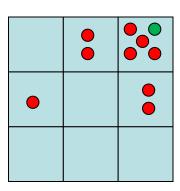

Representation: Particles

- Our representation of P(X) is now a list of N particles (samples)
 - Generally, N << |X|
 - Storing map from X to counts would defeat the point

- So, many x may have P(x) = 0!
- More particles, more accuracy
- For now, all particles have a weight of 1

Particles:

(3,3)

(2,3)

(3,3)

(3,2)

(3,3)

(3,2) (1,2)

(3,3)

(3,3)

(2,3)

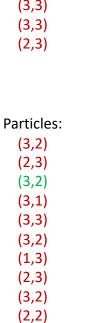

Particle Filtering: Elapse Time

 Each particle is moved by sampling its next position from the transition model

$$x' = \text{sample}(P(X'|x))$$

- This is like prior sampling samples' frequencies reflect the transition probabilities
- Here, most samples move clockwise, but some move in another direction or stay in place
- This captures the passage of time
 - If enough samples, close to exact values before and after (consistent)

Particles: (3,3) (2,3) (3,3) (3,2) (3,3) (3,2) (1,2) (3,3) (3,3) (3,3) (2,3)

Particle Filtering: Observe

Slightly trickier:

- Don't sample observation, fix it
- Similar to likelihood weighting, downweight samples based on the evidence

$$w(x) = P(e|x)$$

$$P(X) \propto P(e|X)P'(X)$$

 As before, the probabilities don't sum to one, since all have been downweighted (in fact they now sum to (N times) an approximation of P(e))

Particles: (3,2) (2,3) (3,2) (3,1) (3,3) (3,2) (1,3) (2,3) (3,2)

Particles:

(2,2)

(3,2) w=.9 (2,3) w=.2 (3,2) w=.9

(3,1) w=.4

(3,3) w=.4

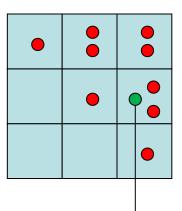

(3,2) w=.9

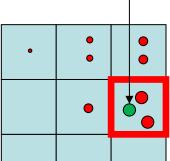

(1,3) w=.1

(2,3) w=.2

(3,2) w=.9

(2,2) w=.4

Particle Filtering: Resample

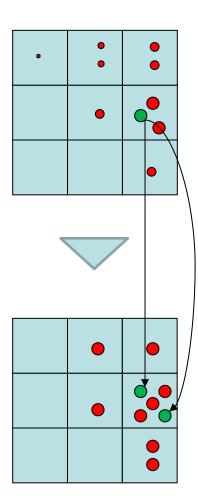

- Rather than tracking weighted samples, we resample
- N times, we choose from our weighted sample distribution (i.e. draw with replacement)
- This is equivalent to renormalizing the distribution
- Now the update is complete for this time step, continue with the next one

Particles:

- (3,2) w=.9
- (2,3) w=.2
- (3,2) w=.9
- (3.1) w=.4
- (3,3) w=.4
- (3,2) w=.9
- (1,3) w=.1
- (2,3) w=.2
- (3,2) w=.9
- (2,2) w=.4

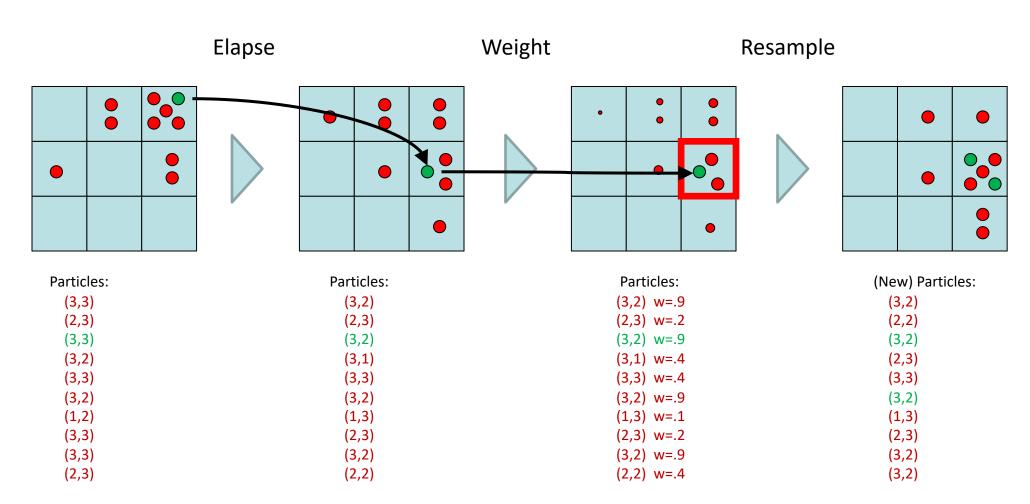

(New) Particles:

- (3,2)
- (2,2)
- (3,2)
- (2,3)
- (3,3)
- (3,2)
- (1,3)
- (2,3)
- (3,2)
- (3,2)

Recap: Particle Filtering

Particles: track samples of states rather than an explicit distribution

Video of Demo – Moderate Number of Particles

Video of Demo – One Particle

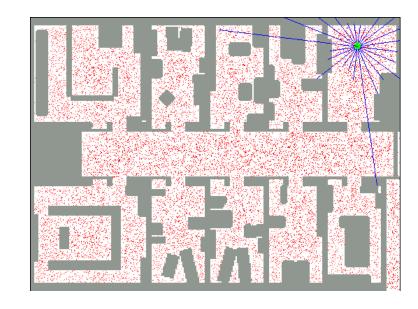

Video of Demo – Huge Number of Particles

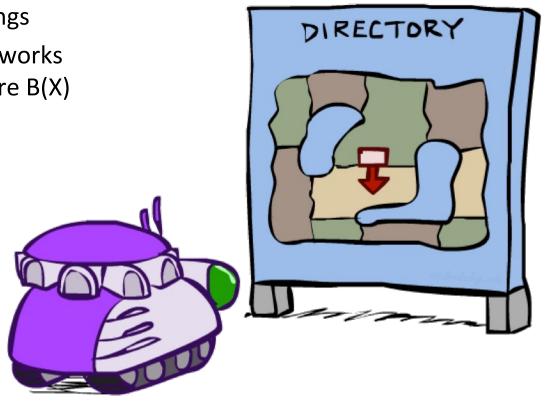

Robot Localization

In robot localization:

- We know the map, but not the robot's position
- Observations may be vectors of range finder readings
- State space and readings are typically continuous (works basically like a very fine grid) and so we cannot store B(X)
- Particle filtering is a main technique

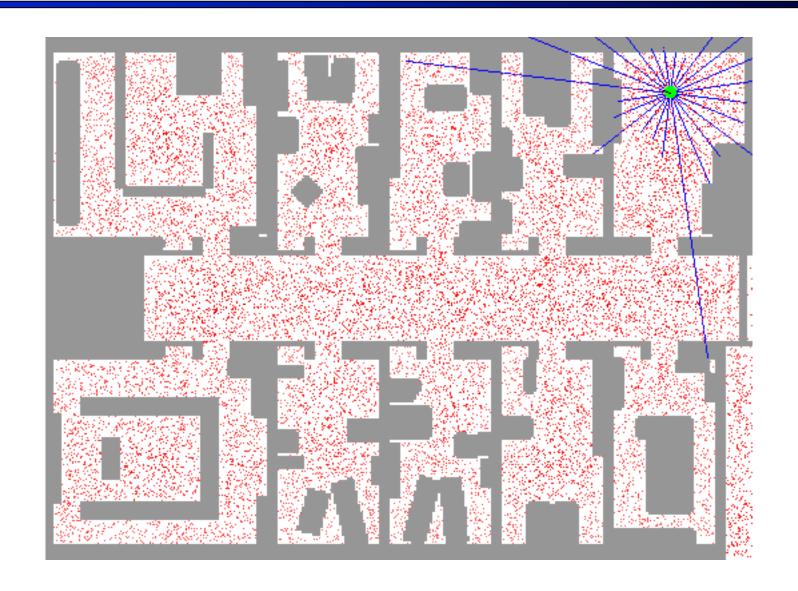

Particle Filter Localization (Sonar)

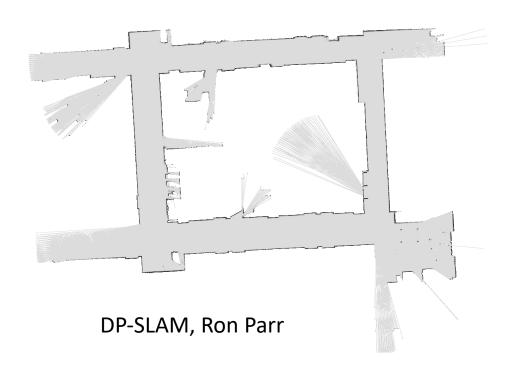

Particle Filter Localization (Laser)

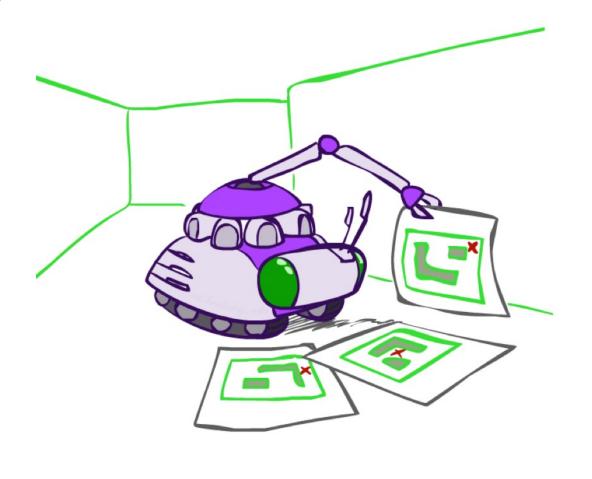

[Video: global-floor.gif]

Robot Mapping

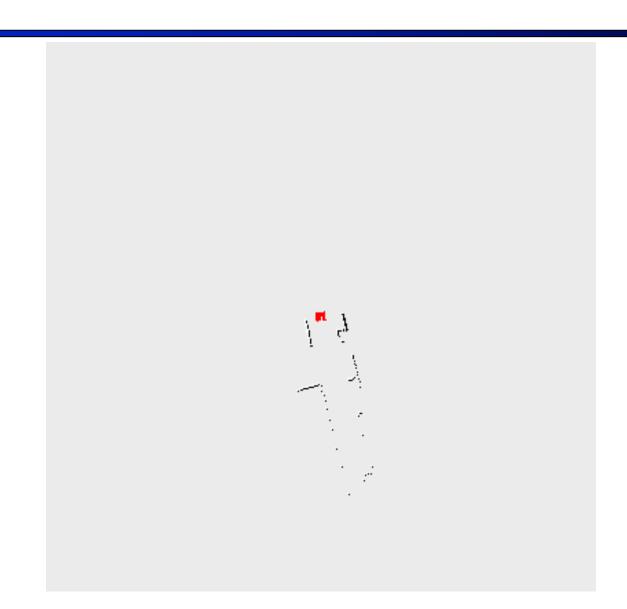

- SLAM: Simultaneous Localization And Mapping
 - We do not know the map or our location
 - State consists of position AND map!
 - Main techniques: Kalman filtering (Gaussian HMMs) and particle methods

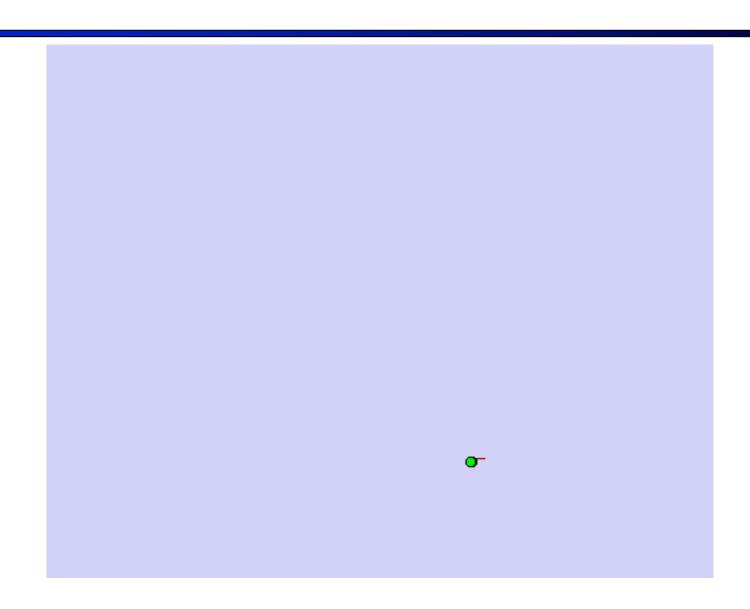

[Demo: PARTICLES-SLAM-mapping1-new.avi]

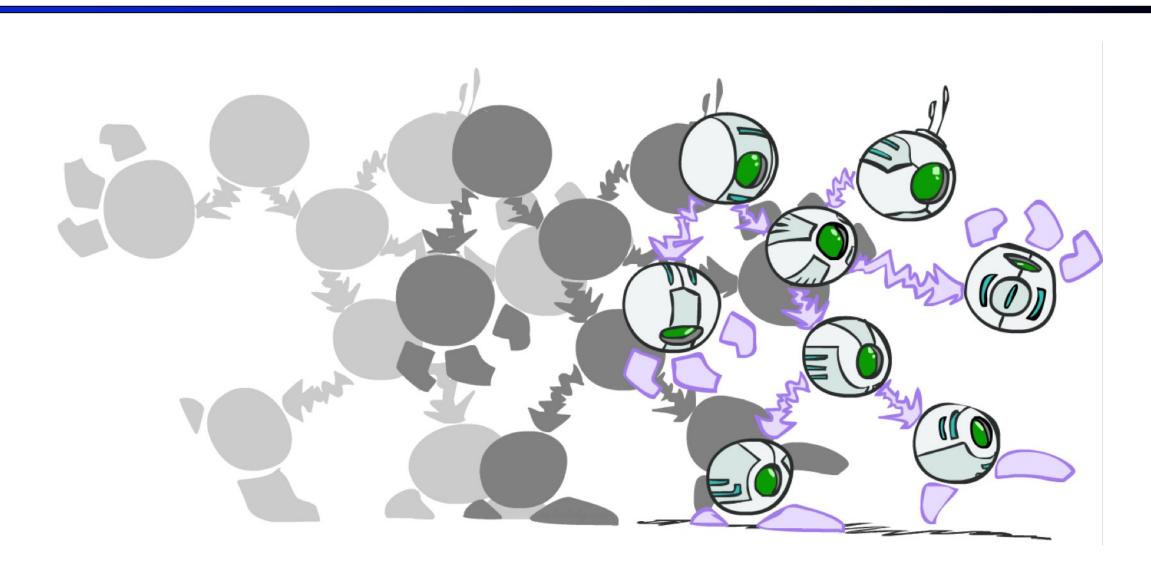

Particle Filter SLAM – Video 1

Particle Filter SLAM – Video 2

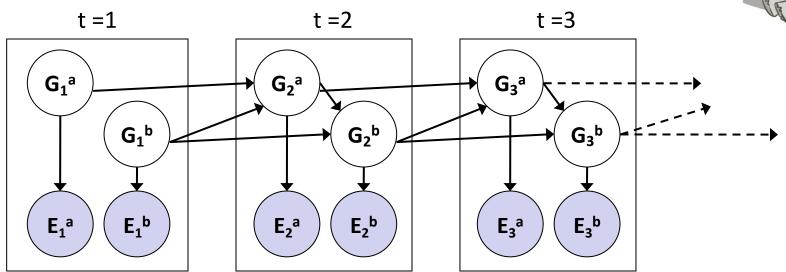

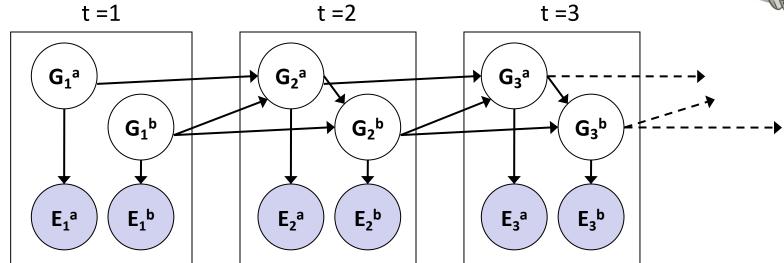

Dynamic Bayes Nets

Dynamic Bayes Nets (DBNs)

- We want to track multiple variables over time, using multiple sources of evidence
- Idea: Repeat a fixed Bayes net structure at each time
- Variables from time t can condition on those from t-1

Dynamic Bayes nets are a generalization of HMMs

Video of Demo Pacman Sonar Ghost DBN Model

DBN Particle Filters

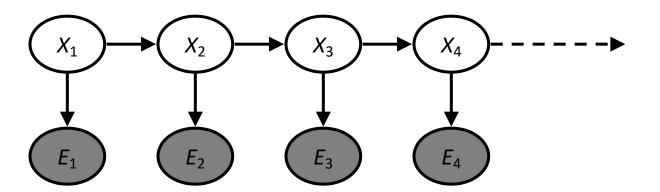

- A particle is a complete sample for a time step
- Initialize: Generate prior samples for the t=1 Bayes net
 - Example particle: $G_1^a = (3,3) G_1^b = (5,3)$
- Elapse time: Sample a successor for each particle
 - Example successor: $G_2^a = (2,3) G_2^b = (6,3)$
- Observe: Weight each <u>entire</u> sample by the likelihood of the evidence conditioned on the sample
 - Likelihood: $P(E_1^a | G_1^a) * P(E_1^b | G_1^b)$
- Resample: Select prior samples (tuples of values) in proportion to their likelihood

Most Likely Explanation

HMMs: MLE Queries

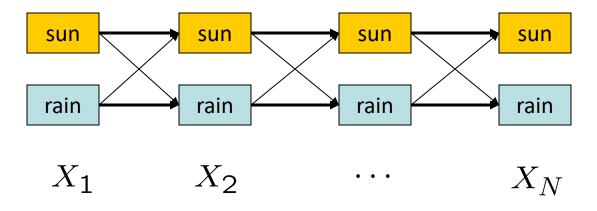

- HMMs defined by
 - States X
 - Observations E
 - Initial distribution: $P(X_1)$
 - Transitions: $P(X|X_{-1})$
 - Emissions: P(E|X)

- New query: most likely explanation: $\underset{x_{1:t}}{\operatorname{arg\,max}} P(x_{1:t}|e_{1:t})$
- New method: the Viterbi algorithm

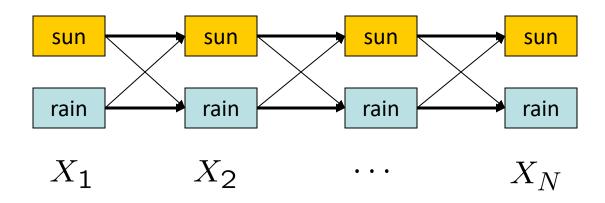

State Trellis

State trellis: graph of states and transitions over time

- Each arc represents some transition $x_{t-1} o x_t$
- Each arc has weight $P(x_t|x_{t-1})P(e_t|x_t)$
- Each path is a sequence of states
- The product of weights on a path is that sequence's probability along with the evidence
- Forward algorithm computes sums of paths, Viterbi computes best paths

Forward / Viterbi Algorithms

Forward Algorithm (Sum)

$$f_{t}[x_{t}] = P(x_{t}, e_{1:t})$$

$$m_{t}[x_{t}] = \max_{x_{1:t-1}} P(x_{1:t-1}, x_{t}, e_{1:t})$$

$$= P(e_{t}|x_{t}) \sum_{x_{t-1}} P(x_{t}|x_{t-1}) f_{t-1}[x_{t-1}]$$

$$= P(e_{t}|x_{t}) \max_{x_{t-1}} P(x_{t}|x_{t-1}) m_{t-1}[x_{t-1}]$$

AI in the News

I Know Why You Went to the Clinic: Risks and Realization of HTTPS Traffic Analysis Brad Miller, Ling Huang, A. D. Joseph, J. D. Tygar (UC Berkeley)

Challenge

- Setting
 - User we want to spy on use HTTPS to browse the internet
- Measurements
 - IP address
 - Sizes of packets coming in
- Goal
 - Infer browsing sequence of that user

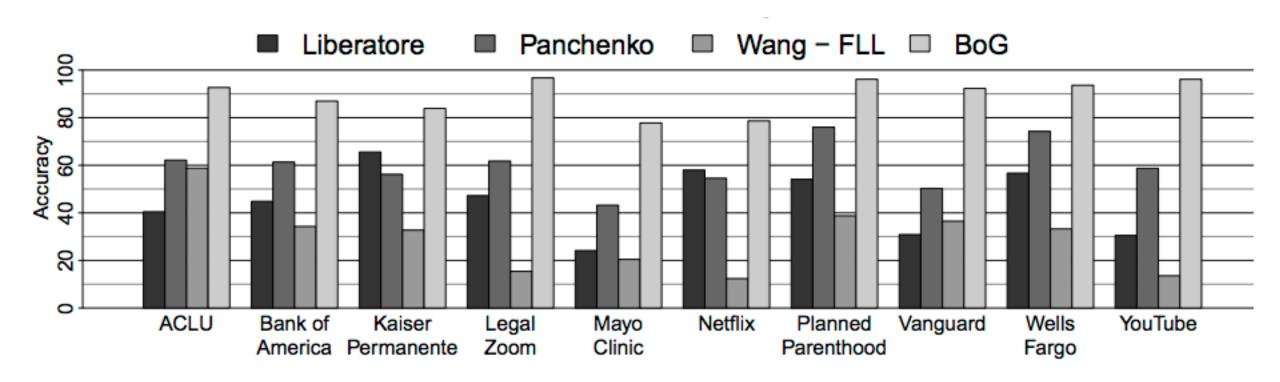

• E.g.: medical, financial, legal, ...

HMM

- Transition model
 - Probability distribution over links on the current page + some probability to navigate to any other page on the site

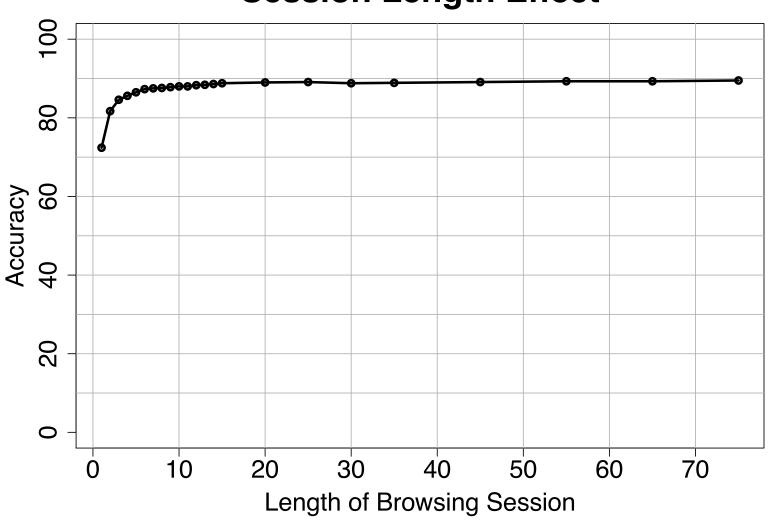

- Noisy observation model due to traffic variations
 - Caching
 - Dynamically generated content
 - User-specific content, including cookies
 - → Probability distribution P(packet size | page)

Speech Recognition

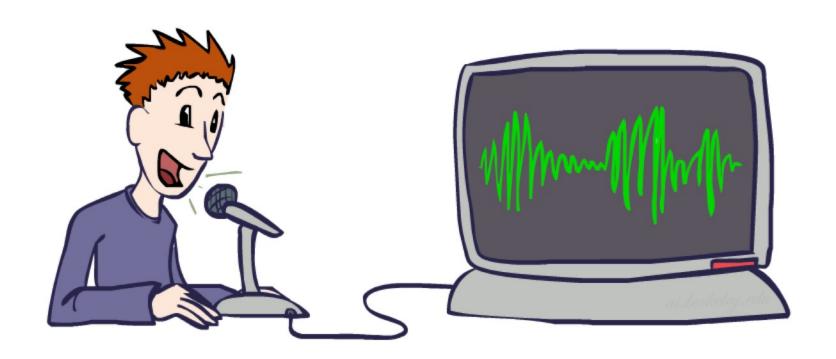

Digitizing Speech

Thanks to Bryan Pellom for this slide!

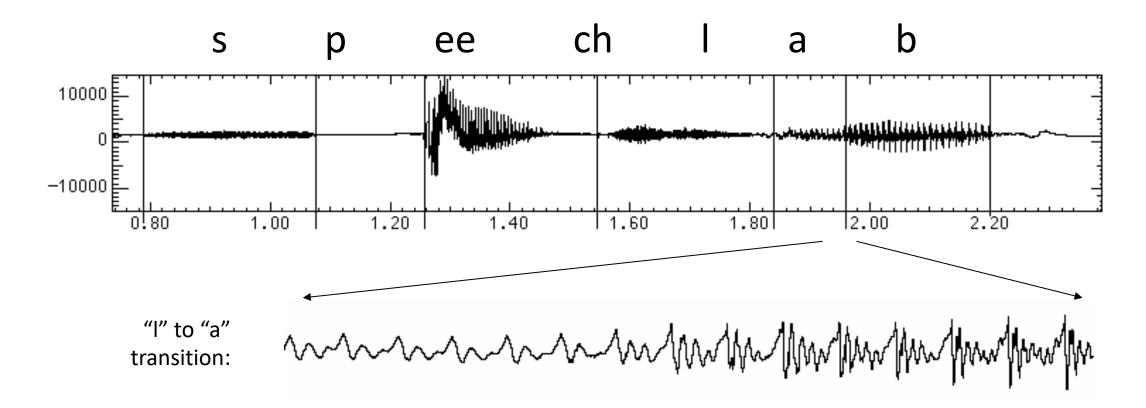

Speech Recognition in Action

Digitizing Speech

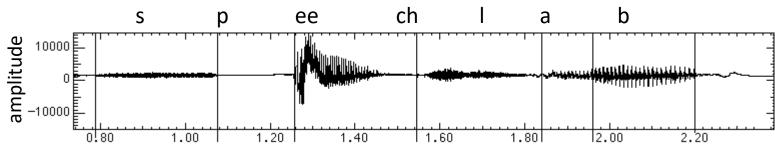

Speech in an Hour

Speech input is an acoustic waveform

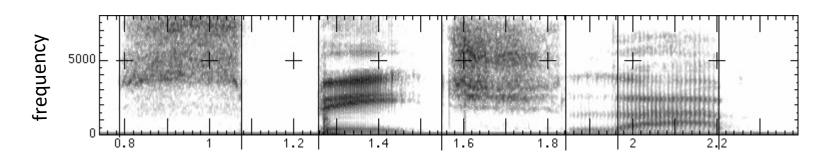

Spectral Analysis

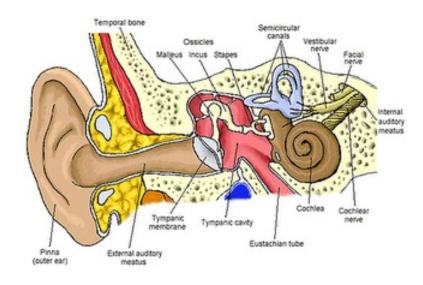

- Frequency gives pitch; amplitude gives volume
 - Sampling at ~8 kHz (phone), ~16 kHz (mic) (kHz=1000 cycles/sec)

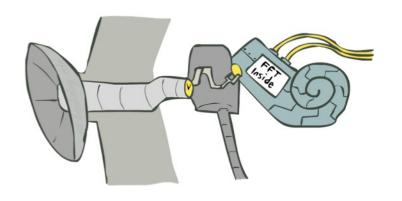

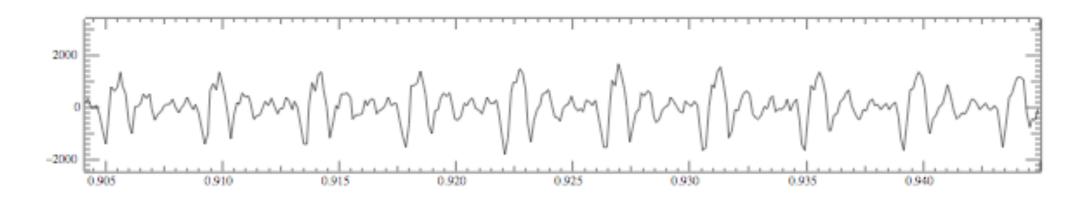

Darkness indicates energy at each frequency

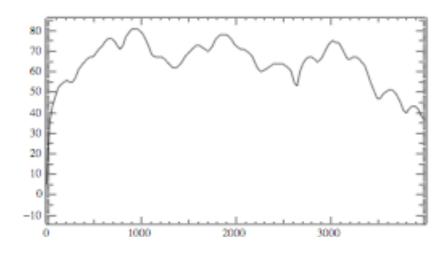

Part of [ae] from "lab"

Complex wave repeating nine times

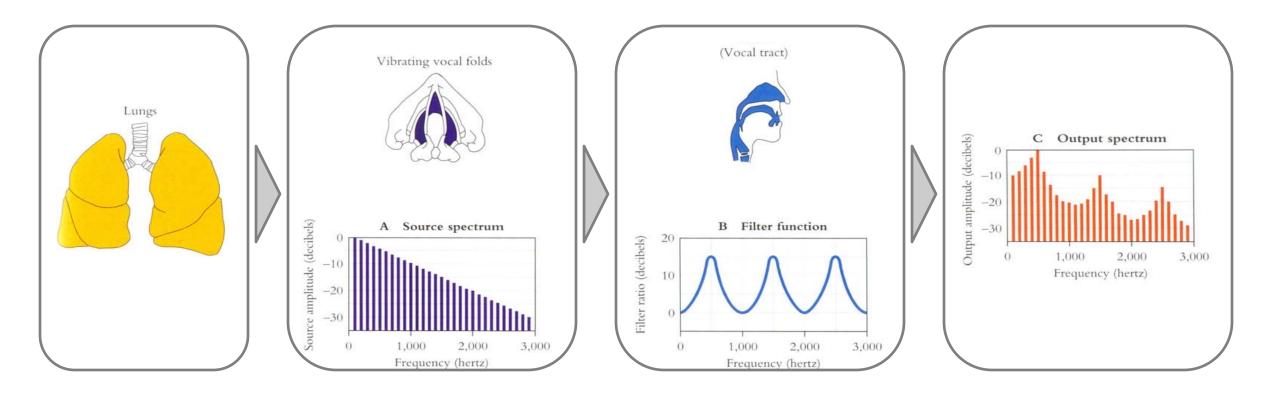

- Plus smaller wave that repeats 4x for every large cycle
- Large wave: freq of 250 Hz (9 times in .036 seconds)
- Small wave roughly 4 times this, or roughly 1000 Hz

Why These Peaks?

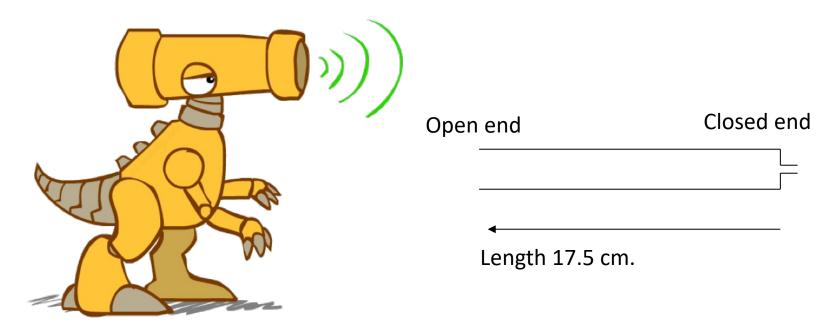

Articulator process:

- Vocal cord vibrations create harmonics
- The mouth is an amplifier
- Depending on shape of mouth, some harmonics are amplified more than others

Resonances of the Vocal Tract

The human vocal tract as an open tube

- Air in a tube of a given length will tend to vibrate at resonance frequency of tube
- Constraint: Pressure differential should be maximal at (closed) glottal end and minimal at (open) lip end

Acoustic Feature Sequence

Time slices are translated into acoustic feature vectors (~39 real numbers per slice)

These are the observations E, now we need the hidden states X

Speech State Space

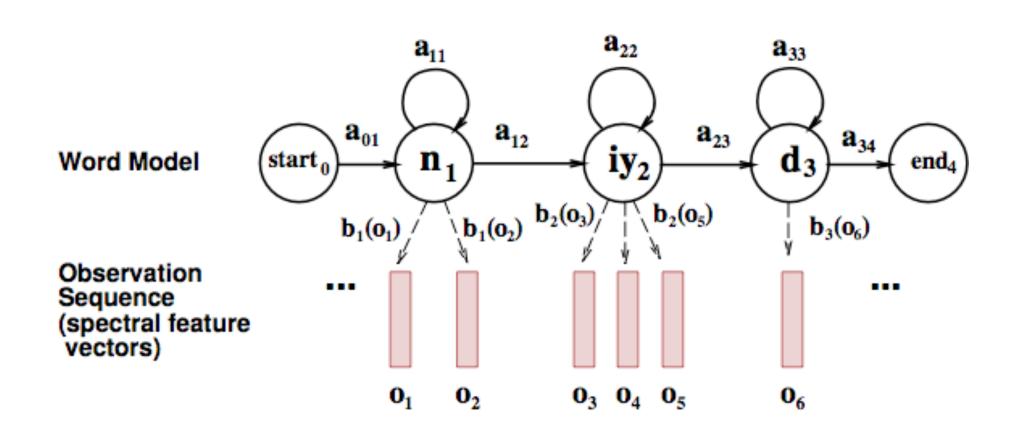

HMM Specification

- P(E|X) encodes which acoustic vectors are appropriate for each phoneme (each kind of sound)
- P(X|X') encodes how sounds can be strung together

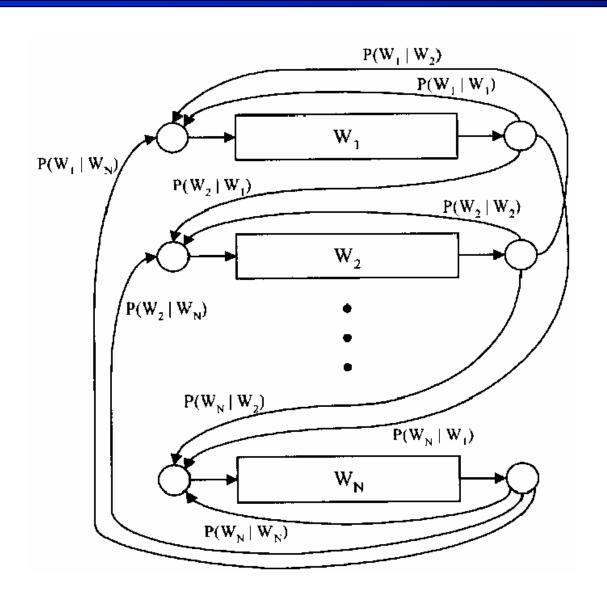

State Space

- We will have one state for each sound in each word
- Mostly, states advance sound by sound
- Build a little state graph for each word and chain them together to form the state space X

States in a Word

Transitions with a Bigram Model

198015222 the first 194623024 the same 168504105 the following 158562063 the world ... 14112454 the door 23135851162 the *

$$\hat{P}(\text{door}|\text{the}) = \frac{14112454}{23135851162}$$
$$= 0.0006$$

Decoding

- Finding the words given the acoustics is an HMM inference problem
- Which state sequence $x_{1:T}$ is most likely given the evidence $e_{1:T}$?

$$x_{1:T}^* = \underset{x_{1:T}}{\operatorname{arg\,max}} P(x_{1:T} | e_{1:T}) = \underset{x_{1:T}}{\operatorname{arg\,max}} P(x_{1:T}, e_{1:T})$$

From the sequence x, we can simply read off the words

Next Time: Bayes' Nets!
